

Orderings of the rationals and dynamical systems

Claudio Bonanno ^{*} Stefano Isola [†]

May 16, 2008

Abstract

This paper is devoted to a systematic study of a class of binary trees encoding the structure of rational numbers both from arithmetic and dynamical point of view. The paper is divided into two parts. The first one is a critical review of rather standard topics such as Stern-Brocot and Farey trees and their connections with continued fraction expansion and the question mark function. In the second part we introduce a class of one-dimensional maps which can be used to generate the binary trees in different ways and study their ergodic properties. This also leads us to study some random processes (Markov chains and martingales) arising in a natural way in this context.

KEYWORDS: Stern-Brocot tree, continued fractions, question mark function, rank-one transformations, transfer operators, martingales

1 Part one: arithmetics

Notational warning: In the sequel we shall use the following notations:

$$\begin{aligned} I &:= [0, 1] \\ J &:= [0, \infty) \cup \{\infty\} \\ \mathbb{Q}_1 &:= \mathbb{Q} \cap [0, 1] \\ \mathbb{Q}_p &:= \left\{ \frac{k}{p^s} : s \in \mathbb{N}, 0 \leq k \leq p^s \right\}, \quad p \geq 2 \end{aligned}$$

1.1 A class of binary trees

We start with the Stern-Brocot (SB) tree $\mathcal{T}$, which is a way to order (and thus to count) the elements of $\mathbb{Q}^+$, the set of positive rational numbers, so that every number appears (and thus is counted) exactly once (see [St], [Br] and, for a modern account, [GKP]). The basic operation needed to construct $\mathcal{T}$ is the *Farey sum*: given $\frac{p}{q}$ and $\frac{p'}{q'}$ in $\mathbb{Q}^+$ set

$$\frac{p}{q} \oplus \frac{p'}{q'} = \frac{p + p'}{q + q'}$$

One notes that the *child* $\frac{p}{q} \oplus \frac{p'}{q'}$ turns out to be in lowest terms whenever the *parents* $\frac{p}{q}$ and $\frac{p'}{q'}$ do. Moreover, the child always lies somewhere in between its parents, e.g., assuming $\frac{p}{q} < \frac{p'}{q'}$, we have $\frac{p}{q} < \frac{p+p'}{q+q'} < \frac{p'}{q'}$.

Starting from the *ancestors* 0 and ∞ (written ‘in lowest terms’) one then writes genealogically one generation after the other using the above operation:

										$\frac{0}{1}$
									$\frac{1}{1}$	$\frac{1}{0}$
								$\frac{1}{2}$	$\frac{2}{1}$	$\frac{3}{0}$
							$\frac{1}{3}$	$\frac{2}{3}$	$\frac{3}{2}$	$\frac{4}{1}$
						$\frac{1}{4}$	$\frac{2}{4}$	$\frac{3}{3}$	$\frac{4}{2}$	$\frac{5}{1}$
					$\frac{1}{5}$	$\frac{2}{5}$	$\frac{3}{4}$	$\frac{4}{3}$	$\frac{5}{2}$	$\frac{6}{1}$
				$\frac{1}{6}$	$\frac{2}{6}$	$\frac{3}{5}$	$\frac{4}{4}$	$\frac{5}{3}$	$\frac{6}{2}$	$\frac{7}{1}$
			$\frac{1}{7}$	$\frac{2}{7}$	$\frac{3}{6}$	$\frac{4}{5}$	$\frac{5}{4}$	$\frac{6}{3}$	$\frac{7}{2}$	$\frac{8}{1}$
		$\frac{1}{8}$	$\frac{2}{8}$	$\frac{3}{7}$	$\frac{4}{6}$	$\frac{5}{5}$	$\frac{6}{4}$	$\frac{7}{3}$	$\frac{8}{2}$	$\frac{9}{1}$
	$\frac{1}{9}$	$\frac{2}{9}$	$\frac{3}{8}$	$\frac{4}{7}$	$\frac{5}{6}$	$\frac{6}{5}$	$\frac{7}{4}$	$\frac{8}{3}$	$\frac{9}{2}$	$\frac{10}{1}$

and so on. The easily verified property which makes the above interesting and useful is the following fact: if $\frac{p}{q}$ and $\frac{p'}{q'}$ are consecutive fractions at any stage of the construction then the unimodular relation $qp' - pq' = 1$ is in force.

Finally, the subtree $\mathcal{F}$ of $\mathcal{T}$ having $\frac{1}{2}$ as root node and vertex set $\mathbb{Q}_1$ is called *Farey tree*. It can be obtained exactly in the same way as $\mathcal{T}$ taking as ancestors $\frac{0}{1}$ and $\frac{1}{1}$ instead of $\frac{0}{1}$ and $\frac{1}{0}$.

Lemma 1.1. *Let $\phi : J \rightarrow I$ be the invertible map defined by $\phi(\infty) = 1$ and*

$$\phi(x) = \frac{x}{x+1} \quad , \quad x \in \mathbb{R}^+$$

Then

$$\phi(\mathcal{T}) = \mathcal{F}$$

Proof It suffice to notice that $\phi(\frac{0}{1}) = \frac{0}{1}$, $\phi(\frac{1}{0}) = \frac{1}{1}$, $\phi(\frac{1}{1}) = \frac{1}{2}$ and for $x, x' \in \mathbb{Q}^+$ we have $\phi(x) \oplus \phi(x') = \phi(x \oplus x')$. $\square$

Another structure we shall deal with is the *dyadic tree* $\mathcal{D}$, whose first two levels are as in $\mathcal{F}$ and then can be constructed from the root node $\frac{1}{2}$ by writing under each vertex $\frac{p}{q}$ the pair $\frac{2p-1}{2q}$ and $\frac{2p+1}{2q}$. The vertex set of $\mathcal{D}$ is $\mathbb{Q}_2$. We shall see later how it is related to $\mathcal{T}$ and $\mathcal{F}$.

1.2 Continued fractions and the $\{L, R\}$ coding

Every $x \in \mathbb{Q}^+$ appears exactly once in the above construction and corresponds to a unique finite path on $\mathcal{T}$ starting at the root node $\frac{1}{1}$ and whose number of vertices equals the *depth* of x , i.e. the level of $\mathcal{T}$ it belongs to. For $x \in \mathbb{Q}_1$ one may just consider the path on the subtree $\mathcal{F}$ which starts at the root node $\frac{1}{2}$ and whose number of vertices is the *rank* of x . For $x \in \mathbb{Q}^+$ we have

$$\text{depth}(x) = [x] + \text{rank}(\{x\}) + 1 \tag{1.1}$$

In order to properly code these paths we start recalling that every rational number $x \in \mathbb{Q}^+$ has a unique finite continued fraction expansion [Kh]

$$x = a_0 + \frac{1}{a_1 + \frac{1}{\ddots + \frac{1}{a_n}}} \equiv [a_0; a_1, \dots, a_n]$$

with $a_0 \geq 0$, $a_i \geq 1$ for $1 \leq i < n$ and $a_n > 1$.

Lemma 1.2. *Let $x \in \mathbb{Q}^+$ then*

$$x = [a_0; a_1, \dots, a_n] \implies \text{depth}(x) = \sum_{i=0}^n a_i$$

Proof. Setting $\text{depth}(\frac{0}{1}) = \text{depth}(\frac{1}{0}) = 0$ we have $\text{depth}(\frac{1}{1}) = 1$. Let now $x = [a_0; a_1, \dots, a_n]$ be such that $\text{depth}(x) = d > 1$. Then, in order to reach the leaf x from the root $\frac{1}{1}$ one has first to move a_0 steps to the right, thus reaching the node $a_0 + \frac{1}{1}$. Then, moving a_1 steps to the left one reaches $a_0 + \frac{1}{a_1 + \frac{1}{1}}$. a_2 further steps to the right reach the point $a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{1}}}$ and so on. In this way, one sees that the path to reach x makes exactly n turns and the length of the blocks within the $(i-1)$ -st and the i -th turn is given by the partial quotient a_i for $1 \leq i < n$, whereas the last block has length $a_n - 1$. More precisely, the blocks moving to the left are related to partial quotients with odd index, those moving to the right to those with even index. It then follows at once that $d = \sum_{i=0}^n a_i$. $\square$

The argument sketched above actually allows us to say more. To this end, we shall first construct a matrix representation of the positive rationals. We start noting that a given $x \in \mathbb{Q}^+$ can be uniquely decomposed as

$$x = \frac{p}{q} \oplus \frac{p'}{q'} \quad \text{with} \quad qp' - pq' = 1$$

The neighbours $\frac{p}{q}$ and $\frac{p'}{q'}$ are thus the parents of x as an element of $\mathcal{T}$. We then identify

$$x \iff \begin{pmatrix} p' & p \\ q' & q \end{pmatrix} \in SL(2, \mathbb{Z})$$

Note that the left column bears on the right parent and viceversa. In this way, the root node yields the identity matrix:

$$\frac{1}{1} = \frac{0}{1} \oplus \frac{1}{0} \iff \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Moreover, given $M \in SL(2, \mathbb{Z})$ which represents the fraction $x \in \mathbb{Q}^+$, the matrix $U M U$ represents the symmetric fraction $1/x$, with

$$U = U^{-1} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

In particular

$$\frac{1}{2} \iff \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} =: L \quad \text{and} \quad \frac{2}{1} \iff \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} =: R$$

More generally, for $k \in \mathbb{N}$,

$$L^k = \begin{pmatrix} 1 & 0 \\ k & 1 \end{pmatrix} \Longleftrightarrow \frac{1}{k+1} \quad \text{and} \quad R^k = \begin{pmatrix} 1 & k \\ 0 & 1 \end{pmatrix} \Longleftrightarrow k+1$$

Now, the point x considered above has in turn a unique pair of (left and right) children, given by

$$\frac{m}{s} \oplus \frac{m+n}{s+t} \quad \text{and} \quad \frac{m+n}{s+t} \oplus \frac{n}{t}$$

respectively. Moreover,

$$\begin{pmatrix} n & m \\ t & s \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} m+n & m \\ s+t & s \end{pmatrix} \Longleftrightarrow \frac{m}{s} \oplus \frac{m+n}{s+t}$$

and

$$\begin{pmatrix} n & m \\ t & s \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} n & m+n \\ t & s+t \end{pmatrix} \Longleftrightarrow \frac{m+n}{s+t} \oplus \frac{n}{t}$$

In other words, the matrices L and R , when acting from the right, move to the left and right child in $\mathcal{T}$, respectively. Together with the argument of the proof given above this yields the following result.

Proposition 1.3. *To each entry $x \in \mathcal{T}$ there corresponds a unique element $X \in SL(2, \mathbb{Z})$, for which we have the following two possibilities:*

- $x = [a_0; a_1, \dots, a_n]$, n even $\Rightarrow X = R^{a_0} L^{a_1} \dots L^{a_{n-1}} R^{a_n-1}$
- $x = [a_0; a_1, \dots, a_n]$, n odd $\Rightarrow X = R^{a_0} L^{a_1} R^{a_2} \dots L^{a_n-1}$

As an easy consequence we have the

Corollary 1.4. *Let $x = [a_0; a_1, \dots, a_n]$ with $a_n > 1$ and n even. Then its left and right children in $\mathcal{T}$ are given by $x' = [a_0; a_1, \dots, a_n - 1, 2]$ and $x'' = [a_0; a_1, \dots, a_n + 1]$, respectively. If instead n is odd the expansions for x' and x'' are interchanged.*

Proof. For n even and larger than one we have $x = [a_0; a_1, \dots, a_n] \Longleftrightarrow X = R^{a_0} L^{a_1} R^{a_2} \dots R^{a_{n-1}} L$. Therefore $x' \Longleftrightarrow X' = R^{a_0} L^{a_1} R^{a_2} \dots R^{a_{n-1}} L$ and $x'' \Longleftrightarrow X'' = R^{a_0} L^{a_1} R^{a_2} \dots R^{a_n}$ which yield the claim. A similar reasoning applies for $n = 0$ and n odd. $\square$

1.3 The infinite coding

One can extend the above construction by associating to each $x \in \mathbb{R}^+$ a unique *infinite* path in $\mathcal{T}$, or else a unique semi-infinite word in $\pi(x) \in \{L, R\}^{\mathbb{N}}$, in the natural way. First, to $x \in \mathbb{R}^+ \setminus \mathbb{Q}^+$ with infinite continued fraction expansion $x = [a_0; a_1, a_2, a_3, \dots]$ there will correspond the (unique) sequence $\pi(x) = R^{a_0} L^{a_1} R^{a_2} L^{a_3} \dots$, where now R and L are nothing but elements of a binary alphabet. For rational x we can proceed as follows. First we set $\pi(\frac{0}{1}) = L^\infty$ and $\pi(\frac{1}{0}) = R^\infty$. Then note that each $x \in \mathbb{Q}^+$ has two infinite paths which agree down to node x : they are those starting with the finite sequence coding the path to reach x from the root node according to Proposition 1.3 and terminating with either RL^∞ or LR^∞ . We shall agree that $\pi(x)$ terminates with RL^∞ or LR^∞ according whether the number of its partial quotients of x is even or odd. Summarizing we have the following coding

- $x = [a_0; a_1, \dots, a_n]$, n even $\Rightarrow \pi(x) = R^{a_0} L^{a_1} \dots R^{a_n} L^\infty$
- $x = [a_0; a_1, \dots, a_n]$, n odd $\Rightarrow \pi(x) = R^{a_0} L^{a_1} \dots L^{a_n} R^\infty$
- $x = [a_0; a_1, a_2, a_3, \dots]$ $\Rightarrow \pi(x) = R^{a_0} L^{a_1} R^{a_2} L^{a_3} \dots$

One easily checks that if $\succ$ denotes the lexicographic order on $\{L, R\}^{\mathbb{N}}$ then

$$x > y \implies \pi(x) \succ \pi(y)$$

Finally, from the above it follows that for an irrational x the infinite path on $\mathcal{T}$ converging to x coincides with the *slow continued fraction algorithm* (see, e.g., [AO]).

1.4 The (extended) question mark function

Given a number $x \in \mathbb{R}^+$ with continued fraction expansion $x = [a_0; a_1, a_2, \dots]$, one may ask what is the number obtained by interpreting the sequence $\pi(x)$ defined in Section 1.3 as the binary expansion of a real number in $(0, 1)$. The number so obtained, denoted $\rho(x)$, writes

$$\rho(x) = 0 . \underbrace{11 \dots 1}_{a_0} \underbrace{00 \dots 0}_{a_1} \underbrace{11 \dots 1}_{a_2} \dots \quad (1.2)$$

or, which is the same,

$$\rho(x) = 1 - \sum_{k \geq 0} (-1)^k 2^{-(a_0 + \dots + a_k)} \quad (1.3)$$

For instance $\rho(1/n) = 1/2^n$ and $\rho(n) = 1 - 1/2^n$ for all $n \geq 1$. Setting $\rho(0) = 0$ and $\rho(\infty) = 1$ we see that $\rho : \mathbb{R}^+ \rightarrow I$ satisfies

$$\rho(x) = ? \circ \phi(x) \quad (1.4)$$

where $\phi : J \rightarrow I$ is the map defined in Lemma 1.1 and $? : I \rightarrow I$ is the *Minkowski question mark function* [M], which for $x = [0; a_1, a_2, \dots]$ is given by

$$?(x) = 0 . \underbrace{00\dots 0}_{a_1-1} \underbrace{11\dots 1}_{a_2} \underbrace{00\dots 0}_{a_3} \dots \quad (1.5)$$

Differently said, for $x \in (0, 1)$ the number $?(x)$ is obtained by interpreting the symbolic sequence corresponding to the path which starts from the root node $\frac{1}{2}$ and approaches x along the Farey tree $\mathcal{F}$ as a binary expansion of a real number in $(0, 1)$.

We now need a simple lemma.

Lemma 1.5.

$$x = [0; a_1, a_2, \dots] \iff 1 - x = \begin{cases} [0; 1 + a_2, a_3, \dots] & \text{if } a_1 = 1 \\ [0; 1, a_1 - 1, a_2, \dots] & \text{if } a_1 > 1 \end{cases}$$

Proof. Upon application of the identity

$$\frac{1}{a + \frac{1}{b}} + \frac{1}{1 + \frac{1}{a-1+\frac{1}{b}}} = 1 \quad \text{and} \quad \frac{1}{1 + \frac{1}{b+c}} + \frac{1}{1 + b + c} = 1 \quad \square$$

Proposition 1.6. *The functions $?$ and ρ satisfy the functional equations*

$$?(x) + ?(1 - x) = 1 \quad , \quad x \in I \quad (1.6)$$

and

$$\rho(x) + \rho(1/x) = 1 \quad , \quad x \in J \quad (1.7)$$

respectively.

Proof. The equation for $?$ follows at once from Lemma 1.5 and (1.5). That for ρ then follows by (1.4). $\square$

Additional properties of ρ are inherited via (1.4) from the following properties of $?$ (see [Sa], [Ki], [VPB], [V]):

- $?(x)$ is strictly increasing from 0 to 1 and Hölder continuous of order $\beta = \frac{\log 2}{\sqrt{5}+1}$

- $x \in \mathbb{Q}_1$ iff $?(x) \in \mathbb{Q}_2$
- x is a quadratic irrational iff $?(x)$ is a (non-dyadic) rational
- $?(x)$ is a singular function: its derivative vanishes Lebesgue-almost everywhere

Figure 1: The $?$ function

For any pair $\frac{p}{q}$ and $\frac{p'}{q'}$ of consecutive fractions in $\mathcal{T}$ the function ρ (as $?$ on $\mathcal{F}$) equates their child to the arithmetic average. For instance we have

$$\rho\left(\frac{p+p'}{q+q'}\right) = \frac{1}{2} \left[\rho\left(\frac{p}{q}\right) + \rho\left(\frac{p'}{q'}\right) \right] \quad (1.8)$$

Therefore the functions ρ and $?$ map the SB tree $\mathcal{T}$ and the Farey tree $\mathcal{F}$, respectively, to the *dyadic tree* $\mathcal{D}$ mentioned above. Note that the set $\mathcal{D}_k$ of dyadic fractions belonging to the first $k+1$ levels of $\mathcal{D}$ is the uniformly spaced sequence $l/2^k$, $l = 0, 1, \dots, 2^k$. Reducing to the lowest terms we get

$$\mathcal{D}_0 = \left(\frac{0}{1}, \frac{1}{1}\right), \quad \mathcal{D}_1 = \left(\frac{0}{1}, \frac{1}{2}, \frac{1}{1}\right), \quad \mathcal{D}_2 = \left(\frac{0}{1}, \frac{1}{4}, \frac{1}{2}, \frac{3}{4}, \frac{1}{1}\right)$$

and so on. Hence, an immediate consequence of the fact that $\rho(\mathcal{T}) = ?(\mathcal{F}) = \mathcal{D}$ is that $\rho(x)$ and $?(x)$ are the asymptotic distribution functions of the sequences of SB fractions and Farey fractions, respectively.

Theorem 1.7. *Set $\mathcal{T}_k := \{\frac{p}{q} \in \mathcal{T} : \text{depth}(x) \leq k\}$. Since*

$$\left| x - \frac{\#\{\frac{p}{q} \in \mathcal{D}_k : \frac{p}{q} \leq x\}}{2^k} \right| \leq 2^{-k}$$

we have

$$\left| \rho(x) - \frac{\#\{\frac{p}{q} \in \mathcal{T}_k : \frac{p}{q} \leq x\}}{2^k} \right| \leq 2^{-k}$$

The same holds for ? with $\mathcal{T}_k$ replaced by $\mathcal{F}_k := \{\frac{p}{q} \in \mathcal{F} : \text{rank}(x) \leq k\}$.

In particular, the Fourier-Stieltjes coefficients of ρ and η are as in the following

Corollary 1.8. *Let*

$$c_n := \int_0^\infty e^{2\pi i n x} d\rho(x)$$

then

$$c_n = \lim_{k \rightarrow \infty} \frac{1}{2^k} \sum_{\substack{p \\ q} \in \mathcal{T}_k} e^{2\pi i n \frac{p}{q}}$$

The same holds for the coefficients of $\mathcal{F}_k$ with $\mathcal{T}_k$ replaced by $\mathcal{F}_k$.

1.5 Permuted trees

Let $X \in SL(2, \mathbb{Z})$ represent a number $x \in \mathbb{Q}^+$ as above and write it as $X = \prod_{i=1}^k M_i$ where $M_i \in \{L, R\}$ and $k = \text{depth}(x)$. Let us denote by $\hat{x}$ the positive rational number represented by the reversed matrix product $\hat{X} = \prod_{i=k}^1 M_i$. Clearly $\text{depth}(x) = \text{depth}(\hat{x})$ but $x = \hat{x}$ if and only if the sequence $M_1 \dots M_k$ is a palindrome. The permutation map $x \mapsto \hat{x}$ yields the permuted version $\hat{\mathcal{T}}$ of the SB tree whose first five levels are shown below (the ancestors $\frac{0}{0}$ and $\frac{1}{0}$ are omitted).

Lemma 1.9. *Under the ancestors $\frac{0}{1}$ and $\frac{1}{0}$, the permuted SB tree $\hat{T}$ can be constructed starting from the root node $\frac{1}{1}$ and writing under each vertex $\frac{p}{q}$ the set of descendants $\{\frac{p}{p+q}, \frac{p+q}{q}\}$.*

Proof. Note that

$$\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} n & m \\ t & s \end{pmatrix} = \begin{pmatrix} n & m \\ n+s & m+t \end{pmatrix} \iff \frac{m+n}{m+n+s+t}$$

and

$$\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} n & m \\ t & s \end{pmatrix} = \begin{pmatrix} n+s & m+t \\ s & t \end{pmatrix} \iff \frac{m+n+s+t}{s+t}$$

In other words, the matrices L and R , when acting from the left give but the left and right descendants, respectively.

Also note that if $\frac{p}{q} = [a_0; a_1, \dots, a_n]$ then $\frac{p}{p+q} = [0; 1, a_0, a_1, \dots, a_n]$ and $\frac{p+q}{q} = [a_0 + 1; a_1, \dots, a_n]$. Therefore

$$\text{depth}\left(\frac{q}{p+q}\right) = \text{depth}\left(\frac{p+q}{q}\right) = \text{depth}\left(\frac{p}{q}\right) + 1$$

This yields the claim. $\square$

Remark 1.10. *The tree $\hat{T}$ has been considered in [CW] where the authors argued that if we read it row by row, and each row from left to right, then for $i \geq 2$ we can write the i -th element in the form $x_i = b(i-2)/b(i-1)$, where $b(n)$ is the number of hyperbinary representation of n , namely the number of ways of writing the integer n as a sum of powers of two, each power being used at most twice. For example $8 = 2^3 = 2^2 + 2^2 = 2^2 + 2 + 2 = 2^2 + 2 + 1 + 1$ and therefore $b(8) = 4$. This property plainly entails that when reading from left to right any sequence of fractions with fixed depth the denominator of each fraction is the numerator of its successor.*

We finally define the corresponding permutation of both the Farey tree $\mathcal{F}$ and the dyadic tree $\mathcal{D}$, denoted $\hat{\mathcal{F}}$ and $\hat{\mathcal{D}}$ respectively. Clearly we have $\hat{\mathcal{F}} = \phi(\hat{T})$ (see Lemma 1.1). Reasoning as above one easily obtains the following simple genealogical rules:

Lemma 1.11. *Under the ancestors $\frac{0}{1}$ and $\frac{1}{1}$, the permuted trees $\hat{\mathcal{F}}$ and $\hat{\mathcal{D}}$ can be constructed starting from the root node $\frac{1}{2}$ and writing under each vertex $\frac{p}{q}$ the sets of descendants $\{\frac{p}{p+q}, \frac{q}{2q-p}\}$ and $\{\frac{p}{2q}, \frac{p+q}{2q}\}$, respectively.*

The first five levels of $\hat{\mathcal{F}}$ are

and the corresponding levels of $\hat{\mathcal{D}}$ are

[illegible]

1.6 Random walks on the permuted trees

We now construct a sequence of random variables $Z_1, Z_2, \dots$ on $\mathbb{Q}^+$ defined recursively in the following way: set $Z_1 = \frac{1}{1}$ and if $Z_k = \frac{p}{q}$ then either $Z_{k+1} = \frac{p}{p+q}$ or $Z_{k+1} = \frac{p+q}{q}$, both with probability $\frac{1}{2}$. The sequence $(Z_k)_{k \geq 1}$ can be regarded as a (symmetric) random walk on $\hat{\mathcal{T}}$.

Theorem 1.12. *The random walk $(Z_k)_{k \geq 1}$ enters any non-empty open interval $(a, b) \subset \mathbb{R}^+$ almost surely.*

Proof. Pick up an irrational number $x = [a_0; a_1, \dots] \in (a, b)$. Then for n large enough we can find a closed subinterval $A \subset (a, b)$ such that the c.f. expansion of each element of A starts as $[a_0; a_1, \dots, a_n, \dots]$. To fix the ideas and with no loss, let n be odd. Then, according to the above and

Proposition 1.3 the path on $\hat{\mathcal{T}}$ starting from the root $\frac{1}{1}$ and entering A (for the first time) will eventually end with the word $W = L^{a_n-1} \dots R^{a_2} L^{a_1} R^{a_0}$. Hence it has the form UW with prefix $U \in \{L, R\}^*$ so that UW does not contain subwords equal to W but W itself. We now proceed by induction on the length ℓ of W , calling W_ℓ the word of length ℓ . If $\ell = 1$ then there is exactly one prefix U of length k for each $k \geq 1$ (e.g. if $W_1 = L$ then $U = R^k$ is the only possible prefix) occurring with probability 2^{-k} . Summing over the prefixes we get $\sum_{k \geq 1} 2^{-k} = 1$. Therefore the claim is true for $\ell = 1$. Now suppose it is true for $\ell = m$. When passing to $\ell = m+1$ either $W_{m+1} = W_m L$ or $W_{m+1} = W_m R$, hence we have two families of paths $UW_m L$ and $UW_m R$, one of which being UW_{m+1} and thus, by the induction hypothesis, having probability $\frac{1}{2}$. We are now left with all paths starting with the ‘bad’ ones and eventually ending with W_{m+1} . But then we can use the self-similarity of the tree and iterate the above construction. Suppose for instance that the ‘bad’ set was $UW_m R$, that is $W_{m+1} = W_m L$. Then at some point we will end up with the alternative $UW_m R U' W_m L$ and $UW_m R U' W_m R$ for some $U' \in \{L, R\}^*$, and the ‘good’ set $UW_m R U' W_m L$ has probability $\frac{1}{2} \cdot \frac{1}{2}$. Iteration of this argument yields the probability $\frac{1}{2^2} + \frac{1}{2^3} + \dots = \frac{1}{2}$ which has to be added to the probability $\frac{1}{2}$ of the initial ‘good’ set $UW_m L$. $\square$

Remark 1.13. *The above result can be easily extended to both $\hat{\mathcal{F}}$ and $\hat{\mathcal{D}}$. However, it seems to be peculiar of the particular permutation which defines these trees, in particular it is plainly false for the original Stern-Brocot tree $\mathcal{T}$ (as well as for $\mathcal{F}$ and $\mathcal{D}$). We shall see later a further generalisation.*

2 Part two: dynamics

We shall now be dealing with a class transformations which generate the permuted trees $\hat{\mathcal{T}}$, $\hat{\mathcal{F}}$ and $\hat{\mathcal{D}}$, respectively, either one generation after the other or in genealogical way, i.e. producing elements with increasing depth.

2.1 Rank one ergodic transformations with dense orbits of rationals

It was noticed in [N] that the sequence x_i of elements of $\hat{\mathcal{T}}$ satisfies the iteration

$$x_{i+1} = \frac{1}{1 - \{x_i\} + [x_i]} \quad , \quad i \geq 0 \quad (2.1)$$

We are thus led to study the map¹ $R : J \rightarrow J$ given by $R(\infty) := 0$ and

$$R(x) := \frac{1}{1 - \{x\} + [x]} \quad , \quad x \in \mathbb{R}^+ \quad (2.2)$$

Proposition 2.1.

1. R is an automorphism of $\mathbb{R}^+$
2. for any $x \in \mathbb{R}^+$, $R(x) \in \mathbb{Q}^+$ if and only if $x \in \mathbb{Q}^+$
3. R counts the set $\mathbb{Q}^+ \cup \{0\} \cup \{\infty\}$ in the following sense: let x_i be the sequence obtained by reading $\hat{T}$ row by row and each row from left to right (except the zero-th one), then $x_i = R^i(\frac{1}{0})$.

Proof. One easily checks that R is one-to-one and onto, with inverse

$$R^{-1}(x) = 2n + 1 - \frac{1}{x} \quad , \quad \frac{1}{n+1} \leq x < \frac{1}{n} \quad , \quad n \geq 0. \quad (2.3)$$

This proves 1. Statement 2 is immediate. Moreover, if $x \in \mathbb{N}$ then $R(x) = 1/(x+1)$ so that $\text{depth}(R(x)) = \text{depth}(x) + 1$. If instead $x = [a_0; a_1, \dots, a_n]$ with $n \geq 1$ then $R(x) = 1/(a_0 + 1 - \{x\})$ so that $\text{depth}(R(x)) = \text{depth}(x)$ since $\text{depth}(1/x) = \text{depth}(x)$ and $\text{rank}(\{x\}) = \text{rank}(1 - \{x\})$. This yields the first part of statement 3. To see the second part we start observing that if we write x in the form $x = (kq + r)/q$ with $k \geq 0$ and $0 \leq r < q$ we have $R(x) = q/(kq + q - r)$. Now if $k = 0$ then $x = r/q$ and $R(x) = q/(q - r)$, namely x and $R(x)$ are left and right descendants of the fraction $r/(q - r)$. If instead $k > 0$ then x is the right descendant of $x' = ((k-1)q + r)/q$ whereas $R(x)$ is the left descendant of $x'' = q/(kq - r)$, and $x'' = R(x')$. $\square$

Remark 2.2. Note that, although the sequence $(x_i)_{i \geq 0}$ defined in (2.4) is dense in $\mathbb{R}^+$, it ‘diffuses’ only logarithmically. Indeed we have $x_i = n$ for $i = 2^n$ and therefore $\sup_{0 < i \leq n} x_i = \mathcal{O}(\log n)$. In fact, from what is proved below it follows that all orbits $\{R^i(x), i \geq 0\}$, $x \in \mathbb{R}^+$, are dense and have this property. An automorphism of the unit circle with similar properties has been constructed in [Bo].

We now restrict to the unit interval and consider two automorphisms on it. The first one is the the map $S : I \rightarrow I$ defined by (see Lemma 1.1)

$$S(x) := \phi \circ R \circ \phi^{-1}(x) \quad (2.4)$$

¹The study of this map was suggested to one us us (C.B.) by Don Zagier

or else by $S(1) = 0$ and

$$S(x) = \frac{1}{2 - \left\{ \frac{x}{1-x} \right\} + \left[\frac{x}{1-x} \right]} \quad , \quad x \in [0, 1) \quad (2.5)$$

Its inverse is

$$S^{-1}(x) = \frac{2nx - 1}{(2n+1)x - 1} \quad , \quad \frac{1}{n+1} \leq x < \frac{1}{n} \quad , \quad n \geq 1 \quad (2.6)$$

The second is the classical *Von Neumann-Kakutani transformation* $T : I \rightarrow I$ given by $T(1) := 0$ and

$$T(x) := x + \frac{3}{2^{n+1}} - 1 \quad , \quad 1 - \frac{1}{2^n} \leq x < 1 - \frac{1}{2^{n+1}} \quad , \quad n \geq 1 \quad (2.7)$$

It was defined in [VN] and is also called *van der Corput's transformation* or else *dyadic rotation*.

Figure 2: The maps S (left) and T (right).

Theorem 2.3. *We have the following commutative diagram*

$$\begin{array}{ccccc} J & \xrightarrow{\phi} & I & \xrightarrow{?} & I \\ R \downarrow & & \downarrow S & & \downarrow T \\ J & \xrightarrow{\phi} & I & \xrightarrow{?} & I \end{array}$$

Proof. The left half follows immediately from (2.4). To see the right half part let $x \in (0, 1)$ be given by $x = [0; a_1, a_2, \dots]$. We have $\frac{x}{1-x} = [0; a_1 - 1, a_2, \dots]$ so that

$$\left[\frac{x}{1-x} \right] = \begin{cases} a_2 & \text{if } a_1 = 1 \\ 0 & \text{if } a_1 > 1 \end{cases}, \quad \left\{ \frac{x}{1-x} \right\} = \begin{cases} [0; a_3, a_4, \dots] & \text{if } a_1 = 1 \\ [0; a_1 - 1, a_2, \dots] & \text{if } a_1 > 1 \end{cases}$$

and therefore

$$S(x) = \begin{cases} (2 + a_2 - [0; a_3, a_4, \dots])^{-1} & \text{if } a_1 = 1 \\ (2 - [0; a_1 - 1, a_2, \dots])^{-1} & \text{if } a_1 > 1 \end{cases} \quad (2.8)$$

Using Lemma 1.5 this becomes

$$S(x) = \begin{cases} [0; a_2 + 1, 1, a_3 - 1, a_4, \dots] & \text{if } a_1 = 1 \\ [0; 1, 1, a_1 - 2, a_2, \dots] & \text{if } a_1 > 1 \end{cases} \quad (2.9)$$

where for $a_k \geq \ell \geq 1$ for some $k \geq 1$ we set

$$[a_0; a_1, a_2, \dots, a_{k-1}, a_k - \ell, a_{k+1}, \dots] = [a_0; a_1, a_2, \dots, a_{k-1} + a_{k+1}, \dots]$$

if $a_k = \ell$. On the other hand, the map $T(x)$ is also named dyadic rotation because of the following fact (see, e.g. [PF], p.120): if we expand $x \in [0, 1]$ in base two, i.e. we write $x = \sum_{k=0}^{\infty} \omega_k 2^{-k-1} = 0.\omega_1\omega_2\dots$ with $\omega_k \in \{0, 1\}$, it acts as $T(0.111\dots) = 0.000\dots$ and for $n \geq 1$

$$T(0.\underbrace{11\dots1}_{n-1}0\omega_{n+1}\omega_{n+2}\dots) = 0.\underbrace{00\dots0}_{n-1}1\omega_{n+1}\omega_{n+2}\dots \quad (2.10)$$

Therefore if $x = [0; a_1, a_2, \dots]$ then using (1.5) we find

$$T(?(x)) = \begin{cases} 0.\underbrace{00\dots0}_{a_2}1\underbrace{00\dots0}_{a_3-1}\underbrace{11\dots1}_{a_4}\dots & \text{if } a_1 = 1 \\ 0.1\underbrace{00\dots0}_{a_1-2}\underbrace{11\dots1}_{a_2}\dots & \text{if } a_1 > 1 \end{cases} \quad (2.11)$$

which is identical to what we obtain applying ? to (2.9). $\square$

We now derive some consequences from the above theorem.

Corollary 2.4. *The maps S and T count the sets $\mathbb{Q}_1$ and $\mathbb{Q}_2$, respectively. More specifically, let for instance y_i be the sequence obtained by reading $\hat{\mathcal{F}}$ row by row and each row from left to right (except the zero-th one), then $y_i = S^i(\frac{1}{1})$. A similar statement holds for $\hat{\mathcal{D}}$ and T .*

Proof. Follows at once from Proposition 2.1 and Theorem 2.3. $\square$

Corollary 2.5. *The systems (J, R) and (I, S) are uniquely ergodic and hence $(J, R, d\rho)$ and $(I, S, d?)$ are ergodic.*

Proof. The first statement follows from the above as topological conjugacy preserves unique ergodicity and the system (I, T) has this property. Moreover, the Lebesgue measure dx is T -invariant so that by the above and (1.4) the maps R and S preserve the measures $d\rho$ and $d?$ respectively. $\square$

Corollary 2.6. *The systems (J, R) and (I, S) are of rank one. Moreover they have the same spectrum which is discrete with eigenvalues $e^{2\pi i\alpha}$ for any dyadic rational α .*

Proof. The system (I, T) has this property. Let us briefly recall how this is obtained. One start setting $A(1, n) = [0, 2^{-n})$ for $n \geq 0$ and noticing that T maps in an affine way $A(i, n) = T^{i-1}A(1, n)$ onto $A(i+1, n)$ for $i = 1, \dots, 2^n$. Clearly, these intervals are not ordered lexicographically but in the way induced by T . For example, for $n = 3$ we have $000 \mapsto 100 \mapsto 010 \mapsto 110 \mapsto 001 \mapsto 101 \mapsto 011 \mapsto 111$. One may then write the so ordered intervals one above the other, thus making a stack which partitions the whole space. The action of T is then that of climbing up one level in the n -stack but is not defined on the top level. At step $n+1$, i.e. looking at the action of the iterates of T on $A(1, n+1)$, the stack is cutted into two equal halves and the right half is stacked on the left half. This defines the action of T on a finer partition of the space. This procedure eventually leads to the knowledge of T on the whole space. Finally, to get the same property for (I, S) it will suffice to follow the above procedure with the family of intervals $B(i, n) = \phi^{-1}(A(i, n))$ (stacked in same order). Clearly, although all the intervals $A(i, n)$, $i = 1, \dots, 2^n$ do have the same length 2^{-n} , the corresponding $B(i, n)$ do not. A similar construction can be done for (J, G) with the intervals $C(i, n) = \phi^{-1}(B(i, n))$. The last assertion follows again from the same property for (I, T) along with topological conjugacy (see, e.g., [PF], p.23). $\square$

Finally, setting $e_n(x) := e^{2\pi i n x}$, the Fourier-Stieltjes coefficients of ρ are

$$c_n := \int_0^\infty e_n(x) d\rho(x) \quad (2.12)$$

By Corollary 1.8 they can be computed as

$$c_n = \lim_{k \rightarrow \infty} \frac{1}{2^k} \sum_{\frac{p}{q} \in \mathcal{T}_k} e_n\left(\frac{p}{q}\right) \quad (2.13)$$

On the other hand, the unique ergodicity of (J, R) following from Corollary 2.5 ensures that they can also be computed as ergodic means in a uniform way.

Corollary 2.7. *We have, uniformly for $x \in J$,*

$$c_n = \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{k=0}^{N-1} e_n(R^k(x))$$

The same holds for the coefficients of ρ with R replaced by S .

Remark 2.8. *An interesting question is whether $c_n \rightarrow 0$ as $n \rightarrow \infty$ (see [Sa]). A solution to this question would give some insights into the degree of uniformity of the distribution of the dense sequence $\{R^k(x)\}_{k \geq 0}$, $x \in J$, and in particular of the permuted Stern-Brocot sequence obtained setting $x = 1$.*

2.2 Markov maps and transfer operators

We now introduce three non-invertible maps which generate the trees $\hat{\mathcal{T}}$, $\hat{\mathcal{F}}$ and $\hat{\mathcal{D}}$ genealogically, i.e. via descendants. With the notations of Theorem 2.3, the first one is the map $G : J \rightarrow J$ given by

$$G(x) = \begin{cases} \frac{x}{1-x} & \text{if } 0 \leq x < 1 \\ x-1 & \text{if } x \geq 1 \end{cases} \quad (2.14)$$

The second is the *modified Farey map* $F : I \rightarrow I$ given by

$$F(x) = \begin{cases} \frac{x}{1-x} & \text{if } 0 \leq x < \frac{1}{2} \\ 2 - \frac{1}{x} & \text{if } \frac{1}{2} \leq x \leq 1 \end{cases} \quad (2.15)$$

and the third is *doubling map* $D : I \rightarrow I$ given by

$$D(x) = 2x \pmod{1} \quad (2.16)$$

They are expansive orientation preserving piecewise analytic endomorphisms such that the sets $G^{-1}(x)$, $F^{-1}(x)$ and $D^{-1}(x)$ are composed exactly by two points for each x . More specifically

$$\begin{aligned} G^{-1}(x) &= \left\{ \frac{x}{1+x}, x+1 \right\} \quad , \quad x \in J \\ F^{-1}(x) &= \left\{ \frac{x}{1+x}, \frac{1}{2-x} \right\} \quad , \quad D^{-1}(x) = \left\{ \frac{x}{2}, \frac{x}{2} + \frac{1}{2} \right\} \quad , \quad x \in I \end{aligned}$$

Both F and D fix the boundary points 0 and 1, but for F these are *indifferent fixed points*, i.e. $F'(0) = F'(1) = 1$. More specifically, 0 is a *weakly repelling* fixed point whereas 1 is *weakly attracting*. On the other hand we can say that G has two indifferent fixed points at 0 and ∞ .

Theorem 2.9. *The permuted tree $\hat{T}$ can be constructed genealogically from its root $\frac{1}{1}$ by writing under each leaf x the set of descendants $G^{-1}(x)$. The same can be done for $\hat{\mathcal{F}}$ and $\hat{\mathcal{D}}$ starting from their root $\frac{1}{2}$ with the sets of descendants $F^{-1}(x)$ and $D^{-1}(x)$, respectively. Furthermore, we have the following commutative diagram*

$$\begin{array}{ccccc} J & \xrightarrow{\phi} & I & \xrightarrow{?} & I \\ G \downarrow & & \downarrow F & & \downarrow D \\ J & \xrightarrow{\phi} & I & \xrightarrow{?} & I \end{array}$$

Proof. The first assertion follows from Lemma 1.9, eq. (2.22) and Lemma 1.11. The proof of the conjugation between G and F is immediate. That for F and D can be obtained reasoning along the same lines as in the proof of Theorem 2.3, starting from the observation that D acts as the shift on binary expansions whereas the action of F is the Farey shift $[0; a_1, a_2, \dots] \mapsto [0; a_1 - 1, a_2, \dots]$ on the interval $[0, \frac{1}{2}]$ and $[0; 1, a_2, \dots] \mapsto 1 - [0; a_2, \dots]$ on $(\frac{1}{2}, 1]$. Then use Lemma 1.5. We leave the details to the interested reader. $\square$

Remark 2.10. Conversely, using the maps G , F and D one can retrace the path from a leaf x in any of the trees $\mathcal{T}$, $\mathcal{F}$ or $\mathcal{D}$ back to the root. For instance, for $x \in \mathcal{T}$ let $X = \prod_{i=1}^k M_i$ be the element which uniquely

represents x in $SL(2, \mathbb{Z})$ with $k = \text{depth}(x)$, according to Proposition 1.3. One then sees that the following rule is in force: if $G^{(i-1)}(x) < 1$ then $M_i = L$, $G^{(i-1)}(x) > 1$ then $M_i = R$, for $i = 1, \dots, k$ with $k = \text{depth}(x)$ so that $G^k(x) = 1$.

Remark 2.11. The map D preserves the Lebesgue measure dx on I , whereas the map F preserves the a.c. infinite measure $\mu(dx) = dx/x(1-x) = (\frac{d}{dx} \log \phi^{-1}(x)) dx$ on I , as one easily checks. This entails that G preserves the (infinite) measure $\nu(dx) = \mu \circ \phi(dx) = dx/x$ on J .

Note that the entropy of $(I, F, d\mu)$ is zero (as well as that of $(J, G, d\nu)$). On the other hand, from the above theorem it follows that also the measure $d?$ is invariant under F (as well as $d\rho$ for G) and the entropy of $(I, F, d?)$ is $\log 2$. Therefore $d?$ is the *measure of maximal entropy* for (I, F) (as well as $d\rho$ for (J, G)).

To the map G we associate a *generalised transfer operator* L_q acting on $f : J \rightarrow \mathbb{C}$ as

$$(L_q f)(x) = \sum_{y \in G^{-1}(x)} \frac{f(y)}{|G'(y)|^q} \quad (2.17)$$

or else

$$(L_q f)(x) = \frac{1}{(1+x)^{2q}} f\left(\frac{x}{1+x}\right) + f(x+1) \quad (2.18)$$

where q is a real or complex parameter. We point out that a continuous fixed function for L_q satisfies the functional equation

$$f(x) = f(x+1) + \frac{1}{(1+x)^{2q}} f\left(\frac{x}{1+x}\right) \quad (2.19)$$

which is called *Lewis-Zagier three-term functional equation* and is related to the spectral theory of the hyperbolic laplacian on the modular surface (see [LeZa] and references therein).

In the same way, the operators associated to D and F act on $f : I \rightarrow \mathbb{C}$ as

$$f(x) \mapsto \frac{1}{2^q} f\left(\frac{x}{2}\right) + \frac{1}{2^q} f\left(\frac{x}{2} + \frac{1}{2}\right) \quad (2.20)$$

and

$$f(x) \mapsto \frac{1}{(1+x)^{2q}} f\left(\frac{x}{1+x}\right) + \frac{1}{(2-x)^{2q}} f\left(\frac{1}{2-x}\right) \quad (2.21)$$

respectively. For the spectral theory of an operator closely related to (2.21) see [I] and [BGI].

2.3 Harmonic functions and martingales

Let Φ_s , $s \in \{0, 1\}$, be the inverse branches of G , i.e.

$$\Phi_0(x) = \frac{x}{1+x} \quad , \quad \Phi_1(x) = x+1 \quad (2.22)$$

They satisfy:

$$\Phi_s(1/x) = \frac{1}{\Phi_{1-s}(x)} \quad , \quad s \in \{0, 1\} \quad (2.23)$$

Let moreover $p(s, \cdot)$, $s \in \{0, 1\}$, be a pair of positive Borel functions such that $p(0, x) + p(1, x) = 1$, $\forall x \in J$. We now want to study the Markov chain with state space J where at each step, starting from a state $x \in J$, two transitions are possible towards the states $\Phi_0(x)$ and $\Phi_1(x)$, with probabilities $p(0, x)$ and $p(1, x)$ respectively. Note that for $x = \frac{1}{2}$ and $p(i, x) = \frac{1}{2}$, $i = 0, 1$, this Markov chain reduces to the random walk on $\hat{T}$ discussed in Theorem 1.12. We now briefly adapt to our context some basic facts about canonical Markov chains associated to Markov transfer operators (see [CoRa]; also [CoRa1] for an application to the dyadic transfer operator (2.20)). Let $P : L^\infty(J) \rightarrow L^\infty(J)$ be the Markov operator acting as

$$(Pf)(x) = p(0, x) f(\Phi_0(x)) + p(1, x) f(\Phi_1(x)) \quad (2.24)$$

A measurable function $h : J \rightarrow \mathbb{C}$ satisfying $Ph = h$ is called *P-harmonic*. In the sequel we shall make the further assumption that the transition probabilities satisfy:

$$p(s, 1/x) = p(1-s, x) \quad , \quad s \in \{0, 1\}, \quad \forall x \in J \quad (2.25)$$

The symmetries (2.23) and (2.25) yield at once the following

Lemma 2.12. *The averaging operator $A : L^\infty(J) \rightarrow L^\infty(J)$ acting as*

$$(Af)(x) = \frac{f(x) + f(1/x)}{2} \quad (2.26)$$

commutes with P . In particular, if $h : J \rightarrow \mathbb{C}$ is a bounded P -harmonic function then Ah has the same property.

A positive measure ν is called *P-invariant* if $\nu P = \nu$, i.e. $\int_J Pf \, d\nu = \int_J f \, d\nu$ for all measurable $f : J \rightarrow \mathbb{C}$. In turn, one readily realizes that this condition is equivalent to

$$\frac{d\nu \circ \Phi_s}{d\nu} = p(s, \cdot), \quad s \in \{0, 1\} \quad (2.27)$$

Now, setting $\Omega := \{0, 1\}^{\mathbb{N}}$, a n -dimensional *cylinder* of Ω is a subset of the type $C(i_1, \dots, i_n) = \{\omega \in \Omega : \omega_1 = i_1, \dots, \omega_n = i_n\}$. The cylinder sets generate the topology of Ω and its Borel σ -algebra $\mathcal{F}$.

Given $x \in J$ let $U(x)$ be the closure of the set of all possible paths starting at x , i.e.

$$U(x) = \overline{\cup_{\omega \in \Omega} \{\Phi_{\omega_n} \circ \dots \circ \Phi_{\omega_1}(x), n \geq 1\}} \quad (2.28)$$

This is clearly a compact invariant set, in the sense that if $y \in U(x)$ then $\Phi_i(y) \in U(x)$, $i \in \{0, 1\}$. More generally, a compact subset V of J is called *invariant* if for all $x \in V$ and all $i \in \{0, 1\}$ such that $p(i, x) > 0$ we have $\Phi_i(x) \in V$.

A first basic fact (see [CoRa], Sec. 3.4; or else [Jo], Chap. 2.4) is that for each $x \in J$ there is a unique probability measure $\mathbb{P}_x$ on Ω such that

$$\mathbb{P}_x(C(i_1, \dots, i_n)) = \prod_{k=1}^n p(i_k, \Phi_{i_{k-1}} \circ \dots \circ \Phi_{i_1}(x)) \quad (2.29)$$

The symmetries (2.23) and (2.25) entail the following

Lemma 2.13. *For each $x \in J$ we have*

$$\mathbb{P}_x(C(i_1, \dots, i_n)) = \mathbb{P}_{1/x}(C(1 - i_1, \dots, 1 - i_n)) \quad (2.30)$$

For $\omega \in \Omega$ let $X_k(\omega) = \omega_k$ be the k -th coordinate function on Ω and $\mathcal{Z}_n$ the subalgebra of $C(\Omega)$ generated by the first n coordinates $\{X_k, 1 \leq k \leq n\}$. The $\mathcal{Z}_n$ form a filtration in that $\mathcal{Z}_n \subset \mathcal{Z}_{n+1}$. Note that if $X \in \mathcal{Z}_n$ then

$$\mathbb{E}_x[X] = \sum_{(\omega_1, \dots, \omega_n) \in \{0, 1\}^n} \prod_{k=1}^n p(\omega_k, \Phi_{\omega_{k-1}} \circ \dots \circ \Phi_{\omega_1}(x)) X(\omega_1, \dots, \omega_n)$$

In particular, if there is $h : J \rightarrow \mathbb{C}$ s.t.

$$X(\omega_1, \dots, \omega_n) = h(\Phi_{\omega_n} \circ \dots \circ \Phi_{\omega_1}(x))$$

then

$$\mathbb{E}_x[X] = (P^n h)(x) \quad (2.31)$$

Now, having fixed $x \in J$, define

$$W_0(x, \omega) := x \quad \text{and} \quad W_n(x, \omega) := \Phi_{X_n(\omega)} \circ \dots \circ \Phi_{X_1(\omega)}(x), \quad n \geq 1 \quad (2.32)$$

The process $\{W_n(x, \cdot), n \geq 0\}$ defined on $(\Omega, \mathcal{F}, \mathbb{P}_x)$ is a Markov chain on J with initial state x and for any measurable function $f : J \rightarrow \mathbb{C}$ we have

$$\lim_{n \rightarrow \infty} (P^n f)(x) = \lim_{n \rightarrow \infty} \mathbb{E}_x[f(W_n(x, \cdot))] \quad (2.33)$$

Moreover, if $h : J \rightarrow \mathbb{C}$ is a measurable bounded P -harmonic function then we have

$$\begin{aligned} \mathbb{E}_x[h(W_{n+1}(x, \cdot)) | \mathcal{Z}_n] &= \sum_{\omega_{n+1} \in \{0,1\}} p(\omega_{n+1}, x) h(\Phi_{\omega_{n+1}} \circ \dots \circ \Phi_{\omega_1}(x)) \\ &= (Ph)(\Phi_{\omega_n} \circ \dots \circ \Phi_{\omega_1}(x)) \\ &= h(\Phi_{\omega_n} \circ \dots \circ \Phi_{\omega_1}(x)) \\ &= h(W_n(x, \cdot)) \end{aligned}$$

In other words the sequence of random variables $\{h(W_n(x, \cdot)), n \geq 0\}$ on $(\Omega, \mathcal{F}, \mathbb{P}_x)$ is a bounded martingale (relative to the filtration $\{\mathcal{Z}_n, n \geq 1\}$) and therefore it converges pointwise $\mathbb{P}_x$ -a.e. The limit random variable $H(x, \cdot) = \lim_{n \rightarrow \infty} h(W_n(x, \cdot))$ satisfies

$$H(x, \omega) = H(\Phi_{\omega_1}(x), \sigma\omega) \quad (2.34)$$

where $\sigma : \Omega \rightarrow \Omega$ is the left shift acting as $(\sigma\omega)_i = \omega_{i+1}$. A bounded measurable function $H : J \times \Omega \rightarrow \mathbb{C}$ satisfying (2.34) is said to be a *cocycle*. Conversely, by (2.31) h may be recovered from the cocycle H as

$$h(x) = \mathbb{E}_x[H(x, \cdot)] \quad (2.35)$$

Remark 2.14. Note that $P : L^\infty(J) \rightarrow L^\infty(J)$ has norm one. Therefore if $h \in L^\infty(J)$ is an eigenfunction of P corresponding to a real and positive eigenvalue then the sequence $\{h(W_n(x, \cdot)), n \geq 0\}$ on $(\Omega, \mathcal{F}, \mathbb{P}_x)$ is a supermartingale, which again converges $\mathbb{P}_x$ -a.e. to a limit cocycle H .

Remark 2.15. As pointed out in [Jo], p.50, eq. (2.35) can be thought of as an analogue of the classical result about the existence of boundary functions for bounded harmonic functions via Poisson integral.

We now discuss two specific Markov chains of the above type, denoted $MC^{(0)}$ and $MC^{(1)}$, corresponding to the choices $q = 0$ and $q = 1$ in (2.17).

2.3.1 The Markov chain $MC^{(0)}$

Setting $q = 0$ in (2.17) we have $\frac{1}{2}L_0 1 = 1$. One can then consider the Markov (i.e. normalised) operator $P^{(0)}$ acting as $P^{(0)}f = \frac{1}{2}L_0 f$. More explicitly,

$$(P^{(0)}f)(x) = \frac{1}{2}f\left(\frac{x}{1+x}\right) + \frac{1}{2}f(x+1) \quad (2.36)$$

Note that if h is $P^{(0)}$ -harmonic then, iterating (2.36) we get

$$h(x) = \sum_{k=0}^{N-1} \frac{1}{2^{k+1}} h\left(\frac{x+k}{x+k+1}\right) + \frac{1}{2^N} h(x+N)$$

We therefore have the

Lemma 2.16. *A bounded function $h : J \rightarrow \mathbb{C}$ is $P^{(0)}$ -harmonic if and only if*

$$h(x) = \sum_{k=0}^{\infty} \frac{1}{2^{k+1}} h\left(\frac{x+k}{x+k+1}\right) \quad , \quad x \in [0, \infty)$$

Moreover,

Lemma 2.17. *Let ρ be as in (1.2). The probability measure $d\rho$ on J is $P^{(0)}$ -invariant.*

Proof. From the fact that the function ρ is the distribution function of the (permuted) Stern-Brocot fractions (cf. Theorem 1.7) and Lemma 1.9 one readily obtains that ρ satisfies the functional equation

$$2\rho(x) = \begin{cases} \rho\left(\frac{x}{1-x}\right) & \text{if } 0 < x < 1 \\ \rho(x-1) + 1 & \text{if } x \geq 1 \end{cases} \quad (2.37)$$

The claim now follows straightforwardly. $\square$

Setting $p(0, x) = p(1, x) = 1/2$ we have that there are no compact invariant sets and according to ([CoRa1], Sec. IV) $h \equiv 1$ is the only bounded continuous $P^{(0)}$ -harmonic function. Moreover, the unique probability measure $\mathbb{P}_x^{(0)}$ on Ω such that

$$\mathbb{P}_x^{(0)}(C(i_1, \dots, i_n)) = 2^{-n} \quad (2.38)$$

is atomless for each $x \in J$. The Markov chain $MC^{(0)}$ is then defined as in (2.32) on the probability space $(\Omega, \mathcal{F}, \mathbb{P}_x^{(0)})$. We summarize the above in the following

Theorem 2.18. For $f \in L^1(\mathbb{R}^+, d\rho)$ we have

$$\lim_{n \rightarrow \infty} (P^{(0)n} f)(x) = \lim_{n \rightarrow \infty} \mathbb{E}_x^{(0)}[f(W_n(x, \cdot))] = \int_0^\infty f d\rho \quad (2.39)$$

Taking $f = 1_{(a,b)}$, $(a, b) \subset \mathbb{R}^+$, this is to be compared with Theorem 1.12.

2.3.2 The Markov chain $MC^{(1)}$

Setting $q = 1$ in (2.17) we have $L_1 g = g$ where $g(x) = 1/x$ is the G -invariant density. We then consider the Markov operator $P^{(1)}$ acting as $P^{(1)} f = g^{-1} L_1(f \cdot g)$, or

$$(P^{(1)} f)(x) = \frac{1}{x+1} f\left(\frac{x}{1+x}\right) + \frac{x}{1+x} f(x+1) \quad (2.40)$$

If h is $P^{(1)}$ -harmonic then

$$h(x) = \sum_{k=0}^{N-1} \frac{x}{(x+k)(x+k+1)} h\left(\frac{x+k}{x+k+1}\right) + \frac{x}{x+N} h(x+N)$$

Lemma 2.19. A bounded function $h : J \rightarrow \mathbb{C}$ is $P^{(1)}$ -harmonic if and only if

$$h(x) = \sum_{k=0}^{\infty} \frac{x}{(x+k)(x+k+1)} h\left(\frac{x+k}{x+k+1}\right) \quad , \quad x \in [0, \infty)$$

Furthermore, the validity of $L_1 g = g$ is equivalent to the fact that the infinite measure $\nu(dx) = dx/x$ on J is $P^{(1)}$ -invariant.

Set moreover

$$p(0, \infty) = p(1, 0) = 0 \quad , \quad p(0, 0) = p(1, \infty) = 1 \quad (2.41)$$

and

$$p(0, x) = \frac{1}{x+1} \quad , \quad p(1, x) = \frac{x}{x+1} \quad , \quad x \in (0, \infty) \quad (2.42)$$

They plainly satisfy the symmetry (2.25). Moreover, from (2.41) it follows that the singletons $\{0\}$ and $\{\infty\}$ are two *disjoint compact invariant sets* and from (2.42) one sees that they are the only invariant sets of this type.

The Markov chain $MC^{(1)}$ is now defined as in (2.32) on the probability space $(\Omega, \mathcal{F}, \mathbb{P}_x^{(1)})$, where $\mathbb{P}_x^{(1)}$ is the transition measure on Ω arising from the probabilities (2.41) and (2.42). It satisfies the following

Lemma 2.20. *For $x \in (0, \infty)$ the measures $\mathbb{P}_x^{(1)}$ have no atoms. On the other hand, both $\mathbb{P}_0^{(1)}$ and $\mathbb{P}_\infty^{(1)}$ are purely atomic with $\mathbb{P}_0^{(1)} = \delta_{0\infty}$ and $\mathbb{P}_\infty^{(1)} = \delta_{1\infty}$.*

Proof. From (2.22) and (2.42) it follows that the path of length n starting at $x \in [1, \infty)$ and having largest probability is that corresponding to the word $\omega = 1 \cdots 1$. If instead $0 < x < 1$ it corresponds to $\omega = 0 \cdots 0$. On the other hand we have

$$\mathbb{P}_x^{(1)}(C(1, \dots, 1)) = \mathbb{P}_{1/x}^{(1)}(C(0, \dots, 0)) = \prod_{k=0}^{n-1} \frac{x+k}{x+k+1} = \frac{x}{x+n} \rightarrow 0$$

as $n \rightarrow \infty$, proving the first assertion. The last is straightforward. $\square$

Now, a path starting somewhere in J and converging to 0 corresponds to a sequence of the form $(\omega_1, \dots, \omega_n, 0, 0, 0, \dots)$ for some $n \geq 1$. The symmetric sequence $(1 - \omega_1, \dots, 1 - \omega_n, 1, 1, 1, \dots)$ yields a corresponding path which converges to ∞ . By Lemma 2.13, if we let the first path start at x and the second one at $1/x$, all finite equal portions of them have the same probability. We can thus concentrate on the paths starting at x and converging to 0. In turn, these can be put in a one-to-one correspondence with $\mathbb{Q}_2$ via the mapping

$$\mathbb{Q}_2 \ni a = \sum_{i=1}^n \omega_i 2^{-i} \mapsto \omega(a) = (\omega_1, \dots, \omega_n, 0, 0, 0, \dots)$$

Another copy of $\mathbb{Q}_2$ is obtained via the mapping

$$1 - \mathbb{Q}_2 \ni 1 - a = \sum_{i=1}^n (1 - \omega_i) 2^{-i} + 2^{-n} \mapsto \omega(1 - a) = (1 - \omega_1, \dots, 1 - \omega_n, 1, 1, 1, \dots)$$

With the identification $a \leftrightarrow \omega(a)$ we set

$$\mathbb{P}_x^{(1)}(\mathbb{Q}_2) = \sum_{a \in \mathbb{Q}_2} \mathbb{P}_x^{(1)}(\omega(a)) \quad (2.43)$$

so that Lemma 2.20 can be rephrased in the form

$$\mathbb{P}_x^{(1)}(\mathbb{Q}_2) + \mathbb{P}_x^{(1)}(1 - \mathbb{Q}_2) = \delta_x^0 + \delta_x^\infty \quad (2.44)$$

Finally, putting together the above and ([CoRa1], Sec. IV) we get the following

Theorem 2.21. *The space of bounded harmonic functions has dimension two. A basis for it is given by the functions*

$$h_0(x) = 1 \quad \text{and} \quad h_1(x) = w(x) + w(1/x)$$

where

$$w(x) = \mathbb{P}_x^{(1)} \left[\lim_{n \rightarrow \infty} W_n(x, \cdot) = 0 \right] = \mathbb{P}_{1/x}^{(1)} \left[\lim_{n \rightarrow \infty} W_n(1/x, \cdot) = \infty \right]$$

Remark 2.22. *Having fixed $x, y \in J$ let $B(x, y)$ be the tail event*

$$B(x, y) := \{\omega \in \Omega : \lim_{n \rightarrow \infty} W_n(x, \omega) = y\}$$

According to (2.35), the cocycle H_1 associated to h_1 is

$$H_1(x, \omega) = 1_{B(x, 0) \cup B(x, \infty)}(\omega)$$

Note that, eq. (2.44) can be further rephrased as

$$\mathbb{P}_x^{(1)} [B(x, 0)] + \mathbb{P}_x^{(1)} [B(x, \infty)] = \delta_x^0 + \delta_x^\infty \quad (2.45)$$
